INV Inman Valley Land System

Undulating to rolling low hills scattered between Myponga Reservoir and Hindmarsh Valley

- Area: 154.4 km²
- Annual rainfall: 570 835 mm average
- Geology: The Land System occurs within the floors of ancient (Permian age) glacial valleys. Sediments were deposited in these valleys, either by the glaciers or by associated rivers and streams. These sediments are variable, but have a characteristic appearance. They include sandstones and unconsolidated sandy clays, heavy clays and calcareous clays, weakly lithified to shales. Reworking of sandier sediments has occasionally resulted in the accumulation of sand banks. Erosion of the sedimentary beds and adjacent basement rocks from the sides of the valleys has resulted in the deposition of alluvial sediments on creek flats. These are usually clayey sands to sandy clays. There are occasional basement rock outcrops, protruding through the glacial valley sediments. These are mixed sandstones, siltstones and calcareous shales.
- **Topography**: The landscape is one of rolling low hills separated by creek flats up to a kilometre wide, all contained within the broad deep valleys of ancient glaciers. The valleys vary from three to ten kilometres in width, and are up to 200 m deep. The sediments associated with the glaciation have been extensively eroded by streams which are still exhuming the old valleys. These streams include the Hindmarsh, Inman, Boundy, Yankalilla and Bungala Rivers, and Carrickalinga and Wattle Flat Creeks. These either flow westwards to Gulf St. Vincent, or southwards to Encounter Bay.
- **Elevation**: 40 300 m

Relief: Up to 80 m

Soils: Soil variability reflects variations in parent sediments. Sandy to loamy surfaced texture contrast soils predominate, but there are significant areas of cracking clays and deep coarse to medium textured soils. With the exception of the cracking clays which are variable, the soils are acidic at the surface, but vary from acidic to alkaline at depth.

<u>Main soils</u>

Soils formed on clayey glacial valley sediments

- G3a Loamy sand over clay
- F1/F2 Sandy loam over acid neutral brown clay
- F2a Sandy loam over poorly structured brown clay

<u>Minor soils</u>

Soils formed on clayey glacial valley sediments

- E1 Black cracking clay
- E3 Grey-brown cracking clay
- Soils formed over sandy glacial valley sediments
- G5 Sand over acid clay
- H3 Bleached siliceous sand
- I2/I1 Highly leached sand
- J2 Sandy ironstone soil

Soils formed on alluvial sediments

- F1a Sandy loam over brown clay
- F1b Clay loam over brown clay
- F1c Coarse sandy loam over grey sandy clay

- F2b Sandy loam over poorly structured brown clay
- G3b Thick sand over clay
- M1 Deep sandy loam over sandy clay loam
- H3/M1 Deep loamy sand
- M2a Gradational brown clay loam
- M2b Deep black clay loam

Main features: The Inman Valley Land System is characterized by rolling low hills with mainly sandy to light sandy loam soils with clayey subsoils. These account for 75% of the area. The intervening flats are dominated by sandy loam texture contrast soils with clayey subsoils. Cracking clays and deep black or brown clay loams are locally significant on both slopes and flats. The soils of the slopes generally have low natural fertility and are highly susceptible to acidification. Waterlogging caused by perching of water on subsoil clays is common. Poor deep drainage on these slopes has led to widespread landslips in the past. Severe gully erosion and occasional tunnel erosion is also a feature of the slopes. Nevertheless, there is potential for more intensive uses than traditional grazing, provided soil and irrigation management are adapted to the conditions. The soils of the alluvial flats are commonly limited by waterlogging, but there are significant areas where this is not a serious problem, and there are large patches of moderately well drained, fertile loamy soils with excellent productivity potential. Stream bank erosion and sporadic salinization are locally important land management issues.

Soil Landscape Unit summary: 24 Soil Landscape Units (SLUs) mapped in Inman Valley Land System:

SLU	% of area	Main features #
AiC	0.6	Geology: Metasandstones of the Backstairs Passage Formation.
		AiC Rolling low hills and slopes with relief of 50-100 m and slopes of 16-30%.
		AiD Steep to very steep rocky hillslopes of 80-200 m relief and slopes of 30-80%.
		Main soils: <u>Acidic sandy loam over brown clay on rock</u> - K4a (E)
		Acidic sandy loam over red clay on rock - K3 (E)
		Shallow sandy loam on rock - L1a (L) on steeper and rocky slopes
		Deep loam over brown clay - K2/F1 (M) on lower slopes
AvC	0.4	Moderately steep to steep ridges of basement siltstones, sandstones and calcareous
AvD	0.9	shales, occurring as "islands" projecting from the floor of an old glacial valley. The steeper
		slopes have up to 20% surface stone and sporadic rocky outcrop.
		 AvC Rounded low hills, up to 60 m high with slopes of 15-30%. AvD Steep elongate ridges to 10m high with narrow crests and slopes of 30-100%.
		Soils are shallow to moderately deep and include thick sandy loam over brown and red
		clay, medium thickness loam to clay loam over red or brown clay, shallow crumbly loam
		over semi hard carbonate, and shallow stony sandy loam to loam over rock. These soils
		are inherently fertile and well drained, and are generally moderately deep. The slopes of
		AvD restrict its potential uses to grazing, but easier access on AvC provides potential for
		pasture improvement and perennial crops.
HYII	1.8	Eroded land formed on sandy clays and clays of Permian glacial valleys where landslips
HYJJ	0.9	and/or gully erosion are significant features.
HYLL	3.7	HYII Moderately steep to steep hillsides of 20% to 30% slope, with stable or unstable branching erosion gullies.
		HYJJ Individual gullied water courses.
		HYLL Hillslopes up to 60 metres high with gradients of 20% to 30% (but up to 60% in
		places), affected by landslips in the past and/or with high potential for future mass
		movement. Watercourses are usually gullied.
		There is a mixture of sand to loam over yellow and brown mottled clays, and black and
		grey clay soils.
		Main soils: <u>Sandy loam over poorly structured brown clay</u> - F2a (E)
		Sandy loam over acid-neutral brown clay - F1/F2 (C)
		Loamy sand over clay - G3a (L)
		Black cracking clay - E1 (L)
		<u>Grey-brown cracking clay</u> - E3 (L)

i	r	<u> </u>
		Although these soils are inherently fertile and deep (although prone to waterlogging), the fragility of the land restricts land use options. Even once stabilized, the severely
		damaged areas are always vulnerable to renewed erosion.
LBD	0.2	Lower slopes, drainage depressions and creek flats, formed on alluvial clays, sandy clays and minor sands and gravels, derived from the erosion and subsequent deposition of soil and rock material from hillslopes of Barossa Complex rocks.
		LBD Moderately inclined lower slopes; slopes 8-15%.
		The soils are deep, and mostly have sandy to loamy surfaces overlying slowly permeable
		mottled clay subsoils. There are some better drained red gravelly and stony soils formed on colluvium, usually on sloping ground.
		Main soils: <u>Sandy loam over brown or red clay</u> - F1c (V) on slopes
		Gradational red loamy sand - M1a (L) on slopes
		Sandy loam over brown mottled clay - F1a and F1b (L) on creek flats
		These soils are deep, moderately fertile and imperfectly drained (flats) to moderately
		well drained (slopes). All are susceptible to acidification and all are erodible. Most of the
		land is used for grazing. More intensive development requires erosion control.
LKB	0.2	Lower slopes formed on sandy clays and clays derived from the localized reworking of
LKD	3.9	upslope glacial valley sediments. Slopes are up to 6%.
	017	LKB Slopes of less than 3%
		LKC Slopes of 3-6%.
		The soils are predominantly sandy with clayey subsoils, but there are some heavier types.
		Main soils: Thick sand over clay - G3b (V)
		Sandy loam over brown clay - Fla (M)
		Deep black clay loam - M2b (M)
		These soils are deep but inherently infertile and imperfectly drained. They are also
		susceptible to acidification (having low buffering capacities), erosion (to both wind and
		water) if exposed, and may be water repellent. The land provides good grazing with
		potential for irrigation of fodder crops, and has some scope for horticultural
		development where drainage problems can be overcome.
LNA	3.2	Flats and drainage depressions of the major water courses including the Inman, Bungala
LNE	0.6	and Yankalilla and Rivers. Medium to fine grained alluvial sediments underlie the soils.
LNJ	4.2	LNA Broad alluvial flats.
LNO	0.3	LNE Drainage depressions.
		LNJ Drainage depressions with eroded water courses.LNO Drainage depressions with up to 10% saline seepages.
		LNO Drainage depressions with up to 10% saline seepages. The soils are typically variable, but fall into three main groups:
		 loam over clay soils <u>sandy loam over brown clay</u> - F1a (C)
		sandy loam over grey sandy clay - F1c (C)
		sandy loam on poorly structured brown clay - F2b (C)
		<u>clay loam over brown clay</u> - F1b (M)
		- gradational soils <u>deep black clay loam</u> - M2b (L)
		deep loamy sand - H3/M1 (L)
		gradational brown clay loam - M2a (M)
		- sandy soils thick sand over clay - G3b (L)
		deep sandy loam over sandy clay loam - M1 (M)
		These soils are deep but frequently imperfectly drained due to their clayey subsoils.
		However, thick surface soils reduce this problem. The M2 soils are highly fertile, the F1, F2
		and M1 soils are moderately fertile and the G3 and H3/M1 soils have low fertility. Stream
		bank erosion is a widespread problem and particularly difficult to manage on large
		water courses. Salinity, waterlogging and occasional flooding are local problems. Apart
		from these issues, the land has high productive potential, usually enhanced by
I.D.4		availability of supplementary water.
LPA	1.4	Flat alluvial plains in the upper Carrickalinga Creek catchment, formed on gritty alluvial
		sands and sandy clays derived from erosion of glacial valley sediments. The main soil has
		a thick gritty sandy loam surface over a grey sandy clay loam to sandy clay subsoil.
		Main soils: <u>Coarse sandy loam over grey sandy clay</u> - F1c (V)
		<u>Gradational brown clay loam</u> - M2a (L)
		These soils are deep, but subject to waterlogging. Natural fertility is moderately low, and
		the surface soils are prone to acidification. There is some irrigation of fodder crops, but
LiA	0.1	potential for horticulture is limited by impeded drainage.
LIA	0.1	Low lying flats with slopes of less than 1% formed on alluvial clays. The soils are deep with heavy clay subsoils.
		Main soils: <u>Sandy loam over brown clay</u> - F1a (E)

		Deep grey clay loam - M2 (E)
		This land is generally poorly drained due to its low lying position and slowly permeable
		clayey subsoils. Parts are inundated for extensive periods in most years. However, the soils
		are deep and fertile, although marginally saline in places.
LmC	0.2	Gently sloping alluvial fans adjacent to basement rock highs of the neighbouring
LmD	0.2	Strangways Land System. They are underlain by mixed sandy and clayey alluvial
		sediments derived from the erosion of glacial valley sediments and basement rocks.
		LmC Alluvial fans with slopes of 3-10%.
		LmD Alluvial fans with slopes of 10-18%.
		Strongly texture contrast soils are predominant. These have sandy to sandy loam surfaces and medium to fine grained subsoils.
		Main soils: <u>Sandy loam over brown clay</u> - F1a (E)
		Thick sand over clay - G3b (E)
		Deep sandy loam over sandy clay loam - M1 (E)
		Soils are deep but imperfectly drained, a limitation compounded by the additional
		water received from adjacent steep slopes. Erosion potential is consequently high, so
		disturbance should be minimized.
LoB	0.7	Broad flat to gently sloping alluvial plains formed on alluvial clays, sandy clays and minor
LoF	1.4	sands and grits derived from the erosion of glacial valley sediments and basement rocks.
		Slopes are up to 4%.
		LoB Alluvial flats and gentle slopes at Hay Flat with slopes of 1-4%.LoF Alluvial flats of Boundy River with slopes of 0-2%.
		The characteristic soil is a brown clay loam over clay. Sub dominant soils are variable,
		but all deep over alluvium.
		Main soils: <u>Gradational brown clay lo</u> am - M2a (E)
		<u>Deep black clay loam</u> - M2b (L)
		<u>Deep loamy sand</u> - H3/M1 (L)
		<u>Sandy loam over brown clay</u> - F1a (L)
		Main soils are deep, fertile and moderately well drained. Although there are
		waterlogged areas, the land overall is potentially highly productive, with a range of grazing and horticultural land use options. Stream bank erosion is a localized problem in
		LoF.
PtD	4.9	Rolling low hills formed on sandstones and unconsolidated sandy clays. Slopes are up to
PtF	1.3	30% and relief is up to 80 m. The landscape is broken by well defined creek-lines and
		swamps, and by ferricrete (ironstone) rises.
		PtD Gently rolling low hills with slopes of 8-16%.
		PtF Rolling low hills with slopes of 16-30%.
		The soils are predominantly sandy surfaced, with variable subsoils, including firm heavy clays, friable sandy clays, coffee rock and loose sand. The range of soils in these
		cidys, maple sandy cidys, conee fock and loose sand. The range of solis in mese
		landscapes reflects this subsoil variability
		landscapes reflects this subsoil variability. Main soils: Sand over clay - G3a (E) } all on slopes

PuD Undulating low hills with slopes of 6-12%. PuF Gently rolling to rolling low hills with slopes of 12-30%. Most soils have strongly texture contrast profiles with sandy to loamy surfaces and clayey

Sandy loam over acid-neutral brown clay - F1/F2 (E) } all on slopes
Sandy loam over poorly structured brown clay - F2a (L) }
Thick sand over acid clay - G5 (L) }
Grey-brown cracking clay - E3 (M) }
Thick sand over clay - G3b (M) } on lower slopes and narrow alluvial flats
Sandy loam over brown clay - F1a (M) }
These soils are more susceptible to waterlogging than the related soils of PtD / PtF, with
their heavier clay subsoils. Apart from high sheet/rill erosion potential, the steeper slopes
are prone to landslip and tunnel erosion. Any activities which concentrate or increase
subsoil water could activate mass movement, gully or tunnel erosion. Land use options
are therefore limited on PuF and to some extent on PuD . Natural fertility is low to
moderate, and the soils are highly susceptible to acidification.

PROPORTION codes assigned to soils within Soil Landscape Units (SLU):

- (D) Dominant in extent (>90% of SLU)
- (V) Very extensive in extent (60–90% of SLU)
- (E) Extensive in extent (30–60% of SLU)

- (C) Common in extent (20–30% of SLU)
- (L) Limited in extent (10-20% of SLU)
- (M) Minor in extent (<10% of SLU)

Detailed soil profile descriptions:

- E1 <u>Black cracking clay (Endohypersodic-Endocalcareous, Self-mulching, Black Vertosol)</u> Medium thickness black clay with strong granular structure and a self-mulching, cracking surface, overlying a black to dark grey heavy clay with strong blocky structure and variable amounts of soft calcareous segregations. The soil is formed over a grey, strongly slickensided clay (Hindmarsh Clay equivalent), usually deeper than 100 cm.
- E3 <u>Grey-brown cracking clay (Episodic-Endocalcareous, Epipedal, Brown Vertosol)</u> Medium thickness grey clay with coarse subangular blocky structure and surface cracks, overlying a grey to brown heavy clay with strong coarse prismatic structure and up to 50% soft carbonate segregations at variable depth. The soil is formed on a grey heavy clay with well developed slickensides (Hindmarsh Clay equivalent), usually shallower than 100 cm.
- F1a <u>Sandy loam over brown clay (Bleached-Mottled, Hypocalcic, Brown Chromosol)</u> Thick loamy sand to sandy clay loam with a strongly bleached A2 horizon, sharply overlying a yellowish brown, grey and red mottled clay grading to fine grained alluvium.
- F1b Clay loam over brown clay (Bleached-Mottled, Hypocalcic, Brown Chromosol) Thick greyish brown clay loam with a bleached A2 layer, overlying a yellowish brown, grey and red heavy clay with strong blocky structure, grading to a light grey and yellow clay with some carbonate segregations.
- F1c Coarse sandy loam over grey sandy clay (Sodic, Eutrophic, Grey Chromosol) 30 - 70 cm dark grey gritty coarse sandy loam with a bleached A2 horizon, overlying a dark grey sandy clay loam grading to a dark grey and yellow mottled sandy clay to clay.
- F1/F2 <u>Sandy loam over acid neutral brown clay (Eutrophic, Brown Kurosol / Chromosol)</u> Medium thickness firm to hard loamy sand to sandy loam with a bleached A2 layer, abruptly overlying a dark brown, yellowish brown and red blocky clay, grading to a massive clayey sand to sandy clay.
- F2a Sandy loam over poorly structured brown clay (Hypocalcic, Subnatric, Brown Sodosol) Medium thickness dark brown sand to sandy clay loam with a bleached and hard A2 horizon, overlying a dark grey brown and yellow brown mottled heavy clay with strong prismatic structure, grading to a light grey, yellow and red massive sandy clay to clay with minor soft carbonate segregations from 85 cm.

INV

- F2b Sandy loam over poorly structured brown clay (Eutrophic, Mottled-Subnatric, Brown Sodosol) Thick grey brown hard sandy loam with a bleached A2 horizon, overlying a yellow brown, brown and red massive sandy clay loam to sandy clay with coarse columnar structure.
- G3a Loamy sand over clay (Bleached-Mottled, Eutrophic Brown Kurosol) Medium thickness grey brown loamy sand to light sandy clay loam with a bleached A2 horizon, overlying a yellow brown, grey and red mottled clay with coarse prismatic structure, grading to grey and yellow mottled sandy clay from 100 cm.
- G3b Thick sand over clay (Bleached-Mottled, Eutrophic, Brown Kurosol) Thick greyish brown sand to light sandy loam with a bleached A2 horizon, overlying a grey and yellow mottled sandy clay loam, grading to a yellow brown and grey mottled clay with coarse blocky structure.
- **G5** Sand over acid clay (Bleached, Mesotrophic, Brown Kurosol) Thick grey sand to light sandy loam with a bleached A2 horizon containing variable quartz, sandstone and ironstone gravel, overlying a yellow and brown massive sandy clay loam to light clay, grading to weakly indurated yellow, grey and red sandstone.
- H3 <u>Bleached siliceous sand (Acidic, Regolithic, Bleached-Orthic Tenosol)</u> Very thick white sand overlying yellow sand.
- 12/11 <u>Highly leached sand (Parapanic, Humosesquic, Semiaquic Podosol)</u> Grey sand with a very thick bleached A2 horizon, overlying a coffee rock pan, grading to a brown and yellow massive sandy clay loam to light clay forming on soft sandstone at about 150 cm.
- J2 <u>Sandy ironstone soil (Bleached-Ferric, Mesotrophic, Brown Kurosol)</u> Thick grey sand to sandy loam with a bleached and ironstone gravelly A2 horizon, overlying an ironstone gravelly yellow brown and red sandy clay loam to clay, grading to grey, red and yellow sandy clay loam forming in highly weathered kaolinized sandstone deeper than 150 cm.
- M1 <u>Deep sandy loam over sandy clay loam (Bleached-Mottled, Mesotrophic Grey Kandosol)</u> Very thick grey soft loamy sand to sandy loam with a bleached A2 horizon, grading to a grey to brown sandy clay loam, becoming sandier with depth.
- H3/M1 Deep loamy sand (Regolithic, Grey-Orthic / Bleached-Orthic Tenosol) Very thick grey brown loamy sand to sand, grading to a mottled clayey sand to sandy clay loam below 100 cm, over variable coarse to medium textured and gritty alluvium.
- M2a <u>Gradational brown clay loam (Eutrophic, Brown Dermosol)</u> Thick brown clay loam with granular structure, often with gritty lenses, overlying a dark brown well structured light clay, grading to a greyish brown massive clayey sand to sandy clay loam from 75 cm.
- M2b Deep black clay loam (Melanic, Calcic, Black Dermosol) Medium thickness black clay loam to light clay with strong granular structure, overlying a very dark clay with blocky structure and variable amounts of soft calcareous segregations.
