**Abstract**

*Choretrum spicatum* subsp. *continentale* Lepschi is described as new. Notes on distinguishing this taxon from *C. spicatum* F.Muell. subsp. *spicatum* are provided, and both taxa are illustrated.

**Key words:** Santalaceae, *Choretum*, nomenclature, taxonomy, South Australia.

The genus *Choretrum* R.Br. comprises approximately eight species distributed throughout southern temperate Australia, and is currently under revision by the author. Preparation of a treatment of the Santalaceae for the forthcoming revised *Flora of South Australia* has necessitated the description of a new subspecies of *C. spicatum* F.Muell. in advance of the full taxonomic revision of the genus.

*Choretrum spicatum* subsp. *continentale* Lepschi, subsp. nov.

Erect *shrub* 0.8–1.5 m high, green, glabrous. **Branchlets** rigid to more or less flexible, terete, longitudinally ridged, the ridges minutely tuberculate to smooth; fertile branchlets 1.3–2 mm diameter. **Leaves** persistent (retained on the branchlets and gradually weathering away), scale-like, sessile, appressed to ascending (spreading-ascending to spreading when subtending inflorescences), distal portion rarely slightly incurved or, on older leaves, spreading to recurved, triangular to very-narrowly triangular, 1.3–2 mm long, 0.5–0.6 mm wide; base truncate, apex narrowly acute to acute, margin entire to fimbriate. **Inflorescences** of single pedunculate flowers inserted laterally on the branchlets; flower subtended by 10–14 bracts, 4 of which are involucral. **Peduncle** obscured by bracts, 0.3–1 mm long, straight. **Bracts** persistent to fruiting stage, scale-like, sessile, cupped (lowermost bracts occasionally slightly keeled), scarious; ovate to broadly ovate or rounded-triangular, 0.6–1 mm long, 0.4–1.2 mm wide, lunate in cross section; base truncate, apex acute to rounded or acuminate (occasionally shortly so), margin fimbriate. **Flowers** obscurely pedicellate, floral tube and pedicel 1–1.5 mm long; receptacle margin lobed, the lobes depressed triangular to depressed ovate, 0.1 mm long. **Tepals** more or less ovoid, 1–1.3 mm long; apex incurred, prominently hooded and thickened adaxially, with a small tuft of minute hairs on the adaxial surface above the point of filament insertion, more or less smooth to indistinctly longitudinally striate when dry, white, occasionally flushed reddish-maroon (in life and when dry). **Anthers** broadly obovate, 0.3–0.4 mm long; filaments 0.15–0.2 mm long. **Disc** shallowly to moderately lobed, moderately concave, 1–1.5 mm diameter. **Style** 0.15–0.2 mm long; stigma obscurely stellate. **Drupe** subglobose to globose or broadly ellipsoid, longitudinally ribbed (due to ornamentation on endocarp) when dry, 3–4 mm long; epicarp thin, green, flushed pinkish-red with age (including the persistent tepals) in life, drying brownish-green, sometimes flushed deep red-maroon. Endocarp globose or broadly ellipsoid, longitudinally ribbed, c. 3–4 mm long. **Fig. 1.**

**Distribution.** Occurs in south-eastern South Australia in an area bounded approximately by Keith, Coola Coola Swamp and Frances, extending eastwards into Victoria, where it appears to be confined mainly to the western part of the Little Desert National Park. A small number of early collections (the latest from 1952) exist from the eastern portion of the Little Desert and the Dimboola district, but this taxon does not appear to have been collected from these areas in recent times. Records from Wyperfeld National Park in Jeanes (1999) appear to be based on misidentified collections of *C. glomeratum* R.Br.

**Habitat.** Recorded growing in sand (including sand dunes), sand over clay and sandy loam, in heath or open eucalypt woodland (the latter often with a shrubby understory), frequently in low-lying sites and swamps.
Phenology. Flowers recorded in November and January, with plants collected between September and December generally in bud or very young flower. Fruits recorded in January, March and November.

Notes. Taxonomic differences between populations of *C. spicatum* on Kangaroo Island (the type locality) and those on the Australian mainland were noted by the late H.U. Stauffer (in Eichler 1965), who suggested that mainland plants might deserve specific status, an observation repeated by Hewson (1984) and Jessop (1986). Jeanes (1999) also commented on differences in leaf morphology between mainland and Kangaroo Island populations. Studies by the present author have confirmed that mainland populations are taxonomically distinct. As the differences between mainland and Kangaroo Island populations are relatively minor, subspecific rank is considered appropriate.

Subspecies in *Choretrum spicatum* may be distinguished by characters of the vegetative leaves (i.e. those not subtending inflorescences). These are best observed on young growth, as leaves gradually abrade and weather on older growth. In *C. spicatum* subsp. *spicatum* the vegetative leaves are spreading-ascending to spreading or recurved (Fig. 2), whereas in *C. spicatum* subsp. *continentale* vegetative leaves are appressed to ascending (Fig. 1). The orientation of the vegetative leaves is distinctive for each taxon, and can easily be
observed on young shoots without magnification. The distal portion of the leaf in *C. spicatum* subsp. *continentale* may rarely be slightly incurved or spreading to recurved on older leaves, and in very young growth of *C. spicatum* subsp. *spicatum* some appressed to ascending leaves may rarely occur (e.g. Osborn s.n., AD 98008472), but both these states are infrequent, and overall leaf orientation remains diagnostic. Supplementary characters for separating subspecies in *C. spicatum* include narrowly acute to acute leaf apices in *C. spicatum* subsp. *continentale* (vs. very narrowly acute in subsp. *spicatum*) and entire to fimbriate leaf margins (vs. suberose to (usually) fimbriate in subsp. *spicatum*). Leaves in *C. spicatum* subsp. *spicatum* may also be contorted (in lateral view), a state not observed in subsp. *continentale*. Jeanes (1999) suggested leaf length and persistence as possible diagnostic characters for separating mainland and Kangaroo Island populations of *C. spicatum*, but these characters unfortunately have no discriminatory value in separating infraspecific taxa in this species.

From limited field observations in South Australia and Victoria by the author during December 2002, *C. spicatum* subsp. *continentale* apparently occurs in relatively low densities throughout much of its range, with individual plants often growing hundreds of metres from one another. This is supported by anecdotal observations in field notes on specimen labels, especially from Victoria, e.g. “One plant seen” (Clarke 2235), “One plant” (Cornwall LD 13/89), “Only saw two plants in more than 150 miles” (Irvine s.n.), “Extremely rare shrub, only two plants seen” (Willis s.n., MEL 2063113). Jessop (1986) records *Choretrum spicatum* p.p. (= *C. spicatum* subsp. *continentale*) as “rare in the SE [of South Australia]”, and the species is listed as Rare in Barker et al. (2005). Collectors field notes on herbarium specimens suggest that *C. spicatum* subsp. *spicatum* is also not an abundant taxon within its range.

**Etymology.** Named from the Latin *continentalis* (mainland, continent), in reference to this subspecies being restricted to mainland Australia.

**Acknowledgements**

Thanks are due to the directors of AD and MEL for access to collections in their care, Peter Canty (South Australian Department of Environment & Heritage) for assistance with collecting permits for South Australia, Anthony Whalen for his good company during fieldwork, Laurie Adams and Ian Brooker for the Latin diagnosis, and Gilbert Dashorst for the line-drawing.
